

Optimality of  $A^*$  search -

$A^*$  has following properties  $\rightarrow$

- ①  $\rightarrow$  The tree search version of  $A^*$  is optimal if  $h(n)$  is admissible.
- ②  $\rightarrow$  The graph search version of  $A^*$  is optimal if  $h(n)$  is consistent.

$\rightarrow$  let's try to prove the 2<sup>nd</sup> claim :-

If  $h(n)$  is consistent, then the values of  $f(n)$  along any path are non-decreasing.

\* for any node  $n$ , and <sup>for</sup> any successor  $n'$  of  $n$  the following inequality should hold

$$h(n) \leq c(n, a, n') + h(n') \quad \text{--- (A)}$$

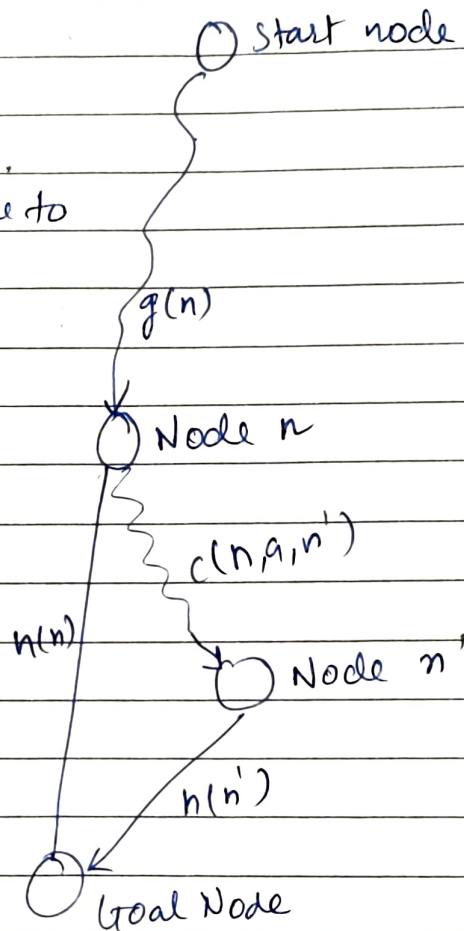

where  $c$  is the cost to go from  $n$  to  $n'$  by performing action  $a$ .

Let's say during our search process, we have reached node  $n$  from start node, and the cost for start node to Node  $n$  is  $g(n)$ .

Now consider a node  $n'$  which is a successor of node  $n$ . Let  $c(n, a, n')$  be the actual cost to go from  $n$  to  $n'$ .

We also have a goal node & let  $h(n)$  be the estimate of cost from node  $n$  to goal node & let  $h(n')$  be the estimate of the cost from node  $n'$  to goal node.

Now, in case of  $A^*$  search we know, that the evaluation function is

$$f(n) = g(n) + h(n) \quad \text{--- (B)}$$

Similarly

$$f(n') = g(n') + h(n') \quad \text{--- (1)}$$

from the above dig  $\rightarrow g(n') = g(n) + c(n, a, n') \quad \text{--- (2)}$

in eq<sup>n</sup> (1) replace value of  $g(n')$  by eq<sup>n</sup> (2)

$$f(n') = g(n) + c(n, a, n') + h(n') \quad \text{--- (3)}$$

In the above eq<sup>n</sup>  $c(n, a, n') + h(n')$  is a part of inequality of eq<sup>n</sup> (A).

In eq<sup>n</sup> (3), so, now if we replace  $c(n, a, n') + h(n')$  with  $h(n)$ , it means we are replacing with a smaller value since eq<sup>n</sup> (A)

$$h(n) \leq c(n, a, n') + h(n')$$

so in eq<sup>n</sup> (3) ~~becomes~~

RHS will become less than  $f(n')$ , means

$$f(n') \geq g(n) + h(n)$$

↳ replacing this with eq<sup>n</sup> (B)

$$f(n') \geq f(n)$$

→ so along any path if we have a node  $n$  & we have a successor  $n'$  of  $n$  then

$$f(n') \geq f(n) \quad \text{so}$$

we see the  $f$  value only increase or remain the same means it is non-decreasing function.

Now we make another claim -

\*\* Whenever  $A^*$  selects a node for expansion, the optimal path to ~~that~~ that node has been found.

Proof  $\rightarrow$

lets say we have 2 different paths from start node to Node  $n$ .

Now out of these two paths lets consider one to be a optimal path & other to be a sub-optimal path

optimal means  $\rightarrow$  g-value along the path will be less than the g-value along the sub-optimal path

Now lets say we have selected node  $n$  through the non-optimal path.

BUT, this cannot happen. why?

That's because there must be a node  $n'$  in the optimal path which is in the frontier list.

lets calculate f-values.

$f_1 = f$ -value of node  $n$  along optimal path

$f_2 = f$ -value of node  $n$  along sub-optimal path.

$f_3 = f$ -value of node  $n'$

$$f_3 \leq f_1$$

} we have seen,  
Along any path  $f$ -value is  
non-decreasing

we will see that

$$f_1 < f_2$$

$$f(n) = g(n) + h(n)$$

$h(n)$  value doesn't depend on which path we followed to reach upto node  $n$ . It is the estimate to the goal node.

since  $h$ -value is same, which  $f$ -value (through optimal path or through non-optimal path) is smaller, will depend on  $g$ -value.

Since  $g$  value of optimal path is less than the  $g$  value of non-optimal path, the  $f$ -value calculated for node  $n$  along this optimal path <sup>( $f_1$ )</sup> is less than the  $f$ -value calculated through sub-optimal path <sup>( $f_2$ )</sup>.

$$\text{So, } f_1 < f_2$$

Now Based on,  $f_3 \leq f_1$  and  $f_1 < f_2$

we can say -

$$f_3 < f_2$$

which means, the  $f$ -value of node  $n'$  is less than the  $f$ -value of node  $n$  calculated along the sub-optimal path.

Remember, Node  $n'$  is in the frontier list, &  $A^*$  algo always selects node to expand from frontier (open) list, it will select the node which has the lowest  $f$ -value.

So as long as we have node  $n'$  in the frontier list, whose  $f$ -value is less than the  $f$ -value of node  $n$  through suboptimal path  $\rightarrow$  then definitely node  $n'$  will be selected instead of node  $n$  for the expansion.

So, it can not happen that we have selected the node  $n$  through the sub-optimal path when we actually have a node  $n'$  in the frontier list.

So, we have proved -

- i) If  $h(n)$  is consistent, then the values of  $f(n)$  along any path are non-decreasing.
- ii) whenever  $A^*$  selects a node  $n$  for expansion, the optimal path ~~through~~ to that node has been found.

Based on above two claims, we can say

\* The sequence of nodes expanded by  $A^*$  using GRAPH-SEARCH is in non-decreasing order of  $f(n)$ .

Hence, the first goal node selected for expansion must be the optimal solution because  $f$  is the true cost for goal nodes (which have  $h=0$ ) and all later goal nodes will be at least as expensive.

If  $C^*$  is the cost of the optimal solution path, then we can say the following:

- $A^*$  expands all the nodes with  $f(n) < C^*$ .
- $A^*$  might then expand some of the nodes with  $f(n) = C^*$  ~~before~~ before selecting a goal node.

\*  $A^*$  is also complete as long as there are only finite number of nodes with cost less than or equal to  $C^*$  (considering all step costs exceed some finite  $\epsilon$  and  $b$  is finite)

$b \rightarrow$  branching factor

\*  $A^*$  is optimally efficient as no other optimal algorithm is guaranteed to expand fewer nodes than  $A^*$ .  $A^*$  expands only those nodes with  $f(n) \leq C^*$ . Any algorithm that does not expand all nodes with  $f(n) < C^*$  runs the risk of missing the optimal solution.
